

Group Project - Project C

A Computational Model of Multiple Representations

Outline. You work for a neuroscience lab interested in exploring connections between multimodal GenAI and a computational model for human-inspired multiple representations. The project goals are open-ended, as your supervisor considers it an exploratory project; still, they seek to better understand how the same idea can be depicted in multiple ways (e.g., through text, depictions, audio, or even smell), different ways to store it (e.g., text, images), and how that relates to different systems, such as AI and humans.

General guidance - You will:

1. Read the paper [CaMeRa: A computational model of multiple representations](#)
2. Build a computational approach to address your supervisor's exploratory needs.

You are free to:

- **Pick a programming language and**
- A GenAI tool of choice.
- Still, your code must be as generalizable as possible, well-documented, and follow the best practices within the chosen technologies.

Technologies

- You will use Git and possibly [Amazon Q Developer for GitHub](#)

Always ensure that you acknowledge the inspiration paper and all resources used to build this work.
